Executive Summary

The 2017 Nechako River Summer Water Temperature and Flow Management Project was undertaken to attempt to prevent mean daily water temperatures in the Nechako River above the Stuart River confluence (at Finmoore) from exceeding 20.0°C between July 20 and August 20. Water temperatures were managed by regulating Skins Lake Spillway releases to control flows in the Nechako River below Cheslatta Falls and at Vanderhoof. In 2017, mean daily water temperatures in the Nechako River above the Stuart River confluence did not exceed 20.0°C.

Over the duration of the 2017 Summer Water Temperature and Flow Management Project (July 10 to August 20), the total volume of water released was 7,937.9 m³/s-d, and the average release during the Project was 189 m³/s.

1.0 Introduction

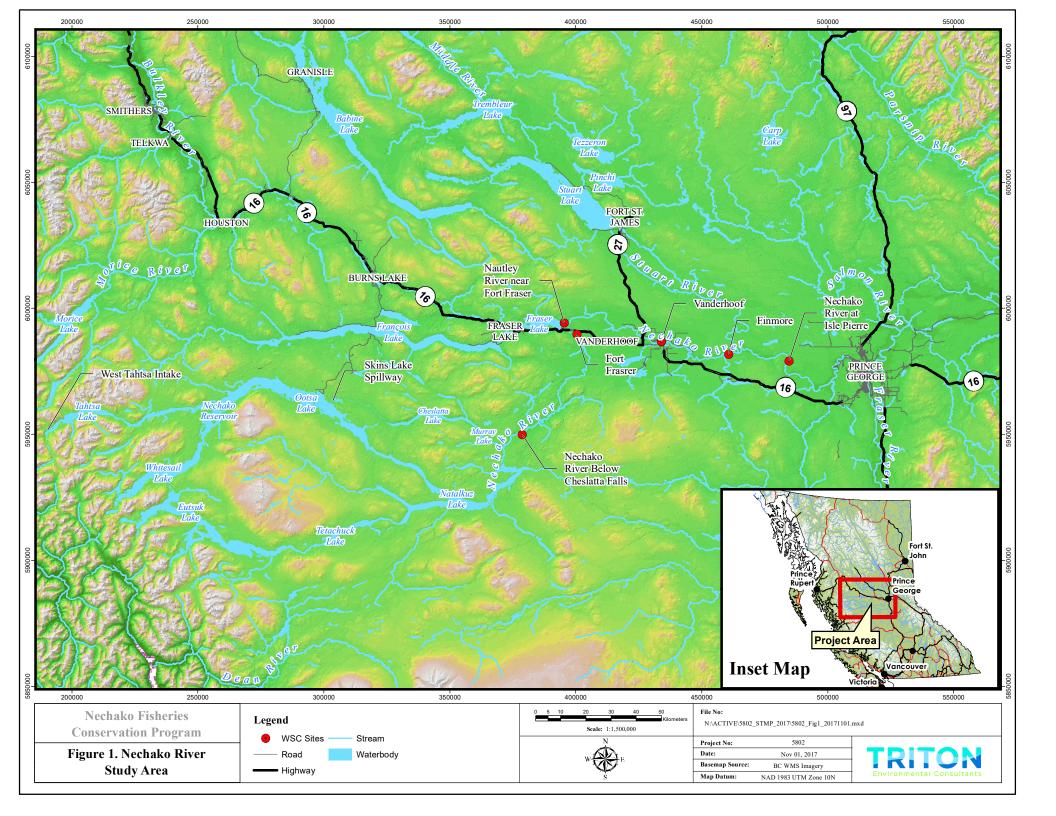

The Nechako River Summer Water Temperature and Flow Management Project (STMP; the Project) was designed and developed in 1982 and has been successfully implemented since 1983. Since 1988, water temperature and flow management projects (Triton 1988 through 1995; Triton 1996 through Triton 2010; Triton 2013 through Triton 2016) have been carried out under the auspices of the Nechako Fisheries Conservation Program (NFCP; NFCP, 2016).

The objective of the Project is to prevent mean daily water temperatures in the Nechako River above the Stuart River confluence (at Finmoore) from exceeding 20.0°C by regulating releases from the Skins Lake Spillway (SLS) to control flows in the Nechako River below Cheslatta Falls (NRBCF) and at Vanderhoof. The Project operates from July 10 to August 20 (the operational period) with the goal of managing water temperatures in the Nechako River at Finmoore between July 20 and August 20 (the water temperature control period, hereafter referred to as the control period). At the completion of the Project, flows in the NRBCF are reduced to fall spawning flows by early September.

The Project study area is shown in Figure 1. Unless otherwise stated, references to water temperature, flow (including releases), and meteorological data are mean daily values. Note that water temperature measurements for the Nechako River above the Stuart River confluence are made at Finmoore and NRBCF (the closest readily accessible locations), while river discharge measurements are made at Vanderhoof (at the Water Survey of Canada discharge measuring site).

This report reviews the 2017 STMP and includes:

- An outline of the method for determining SLS releases and summaries of the 2017 SLS releases for the period July 10 to August 20 inclusive;
- Recorded flows and water temperatures (July 10 to August 20) at various locations along the Nechako River; and
- The volume of cooling water used in the 2017 STMP.

2.0 Methods

Management of the Nechako River flows and water temperatures used water temperature predictions based on five-day meteorological forecasts provided by Environment Canada to determine the schedule of SLS releases required to meet project objectives. The Project uses an unsteady-state flow routing model and an unsteady-state water temperature prediction model designed to compute daily flows and water temperatures in the Nechako River during the operational period of July 20 – August 20 (Envirocon Limited, 1984a,b,c, and 1985).

Daily operations followed the protocol defined in the Settlement Agreement (Anon., 1987), and involved collection of water temperature and river stage and discharge data from five locations in the study area, as well as development of five-day meteorological forecasts.

Water temperatures were obtained daily from temperature loggers maintained in the NRBCF (at Bert Irvine's Lodge), in the Nechako River at Fort Fraser (upstream of the Nautley River), in the Nechako River above the Stuart River confluence, and in the Nautley River. Water temperature data for the NRBCF and the Nautley River were provided by Water Survey of Canada. Water temperature data in the Nechako River at Fort Fraser and in the Nechako River above the Stuart River confluence were obtained using Unidata 6570A temperature probes and downloaded from the Rom Communications (RomComm) website (http://www.romcomm.com/).

River stages were obtained daily from Water Survey of Canada recorders maintained in the NRBCF (Station 08JA017), in the Nechako River at Vanderhoof (Station 08JC001), and in the Nautley River (08JB003), and were obtained daily via the Environment Canada (Water Survey of Canada, WSC) website (https://wateroffice.ec.gc.ca/search/real_time_e.html). Five-day meteorological forecasts were downloaded daily from Environment Canada's server.

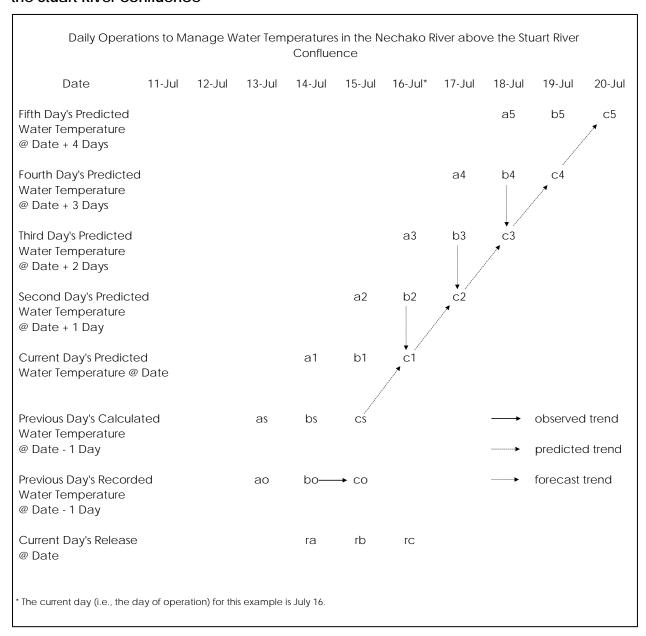

The first 10 days of the operational period, July 10 to July 19, were utilized for system start-up, for initialization of the database required to schedule SLS releases, and to increase flows in the Nechako River from spring flows to the minimum cooling flow of 170 m³/s below Cheslatta Falls. Due to higher than normal reservoir levels and estimated snowpack, discharge at the SLS at the start of the operational period was higher than typical years (144 m³/s). Upon commencement of the operational period on July 10, the recorded flow in the NRBCF was 134 m³/s. The SLS was increased to 226.5 m³/s on July 13 to ensure flows in the NRBCF reached the minimum cooling flow of 170 m³/s by July 20 (the beginning of the water temperature control period).

Throughout the operational period, water temperatures in the Nechako River were calculated daily for the previous day, the current day, and each of the next four days using the unsteady-state flow routing and water temperature prediction models. These calculations were based on recorded and five-day forecast meteorological data, recorded water temperature, and computed flow data. Forecast water temperature

predictions were tabulated and reviewed daily to identify trends in water temperature changes.

These trends are the same as those used in the water temperature and flow management projects since 1984 (Envirocon Ltd., 1985), as illustrated by Table 1.

Table 1. Daily operations to manage water temperatures in the Nechako River above the Stuart River confluence

Assuming the current day is July 16, entries corresponding to the current day's operation are represented by the letter c. Entries co and cs represent the recorded and calculated water temperatures, respectively, for the previous day (July 15).

Entries c1 through c5 represent predicted water temperatures computed using the current day's five-day meteorological forecast and an assumed current day's flow regime. The entry rc represents the current day SLS release required to meet Project objectives.

The following three trends in water temperature changes were reviewed on a day-by-day basis (shown numerically in Appendix 1):

- 1. Observed trend developed from recorded mean daily water temperatures measured in the Nechako River above the Stuart River confluence each day (bo and co in Table 1). The difference in recorded water temperatures for the previous two days is extrapolated over the next five days to determine the observed water temperature trend.
- 2. Predicted trend developed from the predicted water temperatures for the previous day and the following five days (cs, c1, c2, c3, c4, c5, in Table 1). These data represent the predicted trend.
- 3. Forecast trend developed from the difference between the current five-day and previous five-day predictions for the same calendar days (c3 and b4, c2 and b3, c1 and b2 in Table 1). Differences between forecasted data on coincident dates for the current day and the next two days only are averaged and added to the fifth day predicted temperature to determine the trend in forecasted temperatures.

Each day, predicted water temperatures for the five-day forecast period were checked and the three trends calculated. If two of the three trends indicated that the water temperature in the Nechako River above the Stuart River confluence could potentially exceed 19.4°C, then an increase in the SLS release was required. When this occurred, the current day's release was revised and the flow and temperature models were rerun using the modified flow regime. Results of each day's final computer run were subsequently used to initialize water temperatures for the following day's computations. Entries in Table 1 represent each day's final cooling water release and resultant predicted water temperatures.

The following release criteria were used with the three trends identified above to determine the timing and magnitude of Skins Lake Spillway releases:

- 1. When two of the three trends show an increase in water temperature in the Nechako River above the Stuart River confluence, and these trends show that the water temperature could potentially exceed 19.4°C, increase the SLS release according to criteria 2 and 3 below.
- 2. Operate SLS such that flow in the NRBCF ranges between 170 m³/s and 283 m³/s as required, and flow in the Nechako River above the Stuart River confluence (as measured at Vanderhoof) does not exceed 340 m³/s. The flow in the NRBCF is adjusted to be no less than 170 m³/s by the beginning of the control period, and is reduced to approximately 31.9 m³/s by September 1.

- 3. At any time, increase the SLS release from the current level to 453 m³/s to achieve the flow changes in the Nechako River as quickly as possible.
- 4. During cooling periods when two of three trends in forecasted water temperatures are decreasing and these trends indicate that the water temperature could potentially drop below 19.4°C within the forecast period (five days), reduce the SLS release from the current level to 14.2 m³/s.

3.0 Results

Predicted and recorded mean daily water temperatures for the Nechako River above the Stuart River confluence, SLS releases, and changes in SLS releases over the duration of the Project operational period are summarized in Table 2 and Table 3.

Mean daily water temperatures recorded during the control period in the Nechako River above the Stuart River confluence (Figure 2 and Table 4) did not exceed 20.0°C during the 2017 STMP. The respective maximum and minimum mean daily water temperatures recorded during the control period were 19.5°C on August 9 and 16.7°C on August 17. Mean daily water temperatures in the NRBCF, near Fort Fraser and above the Stuart River confluence, and in the Nautley River near Fort Fraser are presented in Appendix B.

Skins Lake Spillway releases and their corresponding flows in the Nechako River below Cheslatta Falls and at Vanderhoof are plotted in Figure 3 (source data are provided in Appendix C). Changes in Skins Lake Spillway releases during the STMP were made on the following dates:

- 1. July 13 Increase to 226 m³/s to increase flow in Nechako River below Cheslatta Falls to STMP base flow by July 20.
- 2. July 18 Decrease to 170 m³/s to ensure flow in Nechako River below Cheslatta Falls is maintained at summer base flow.
- 3. July 30 Increase to 453.1 m³/s to increase flow in the Nechako River below Cheslatta Falls in response to warming trend.
- 4. August 2 Decrease to 283 m³/s to limit flow in Nechako River below Cheslatta Falls to a maximum of 283 m³/s.
- 5. August 10 Decrease to 14.2 m³/s to decrease flow in Nechako River below Cheslatta Falls in response to cooling trend.
- 6. August 13 Increase to 170 m³/s to ensure flow in Nechako River below Cheslatta Falls is maintained at summer base flow.
- 7. August 16 Decrease to 14.2 m³/s to decrease flow in Nechako River below Cheslatta Falls in response to cooling trend and prepare for fall spawning flows.
- 8. September 3 Increase to 32.1 m³/s to ensure flow in Nechako River below Cheslatta Falls is maintained at fall spawning flow.

During the control period, measured flows in the Nechako River below Cheslatta Falls (based on preliminary WSC data from the WSC data collection platform at Bert Irvine's Lodge) ranged between a maximum of 301 m³/s on August 10 and a minimum of 108 m³/s on August 20. Flows measured in the Nechako River at Vanderhoof ranged between a maximum of 339 m³/s on August 9 and a minimum of 174 m³/s on August 20.

4.0 Discussion

The discussion of the 2017 STMP has been divided into three sections. The first section reviews the collection and use of recorded field data, including water temperature, flow, and meteorological data (recorded and forecast). The second section discusses the volume of water used during the 2017 STMP. The third section provides a brief discussion of the application of the Project release criteria.

4.1 Recorded Data

The modelling procedure was initialized using recorded conditions. The quality of the field data used in the modelling process directly affects the accuracy of the computed water temperatures. Therefore, data must be collected accurately and consistently to ensure that random errors are kept to a minimum. Further, consistency in data collection techniques also ensures that, if a bias exists in the data, it remains relatively constant throughout the project.

In 2017, river discharges in the NRBCF and at Vanderhoof, as recorded by the Water Survey of Canada, changed as expected in response to SLS releases (Figure 3). The hourly stage data from the gauging station located on the NRBCF proved useful in verifying the daily predictions of the flow routing model and to account for changes in the local inflow to the Cheslatta/Murray Lakes system (Figure 1).

As previously stated, water temperatures recorded by data loggers were obtained daily from the Rom Communications website for the Nechako River at Fort Fraser and in the Nechako River above the Stuart River confluence.

4.2 Volume of Water Used

The recorded flows in the NRBCF for the 2017 STMP are shown in Figure 4. Also indicated is the minimum cooling flow of 170 m³/s in the Nechako River below Cheslatta Falls, and the Skins Lake Spillway spring base release of 49.0 m³/s, as determined by the NFCP Technical Committee as part of the "Annual Water Allocation" defined in the 1987 Settlement Agreement (Anon., 1987).

The total volume of water released during the 2017 Summer Water Temperature and Flow Management Project operational period was 7,937.9 m³/s-d. The volume released for cooling purposes was 6,068.3 m³/s-d, and is based on the assumed Skins Lake Spillway minimum release for fish protection purposes (part of the Annual Water Allocation) of 49.0 m³/s for the period July 10 to August 15, inclusive, with a reduction to 14.2 m³/s until August 20. The average release during the operational period was 189 m³/s. Volume calculations are presented in Appendix E.

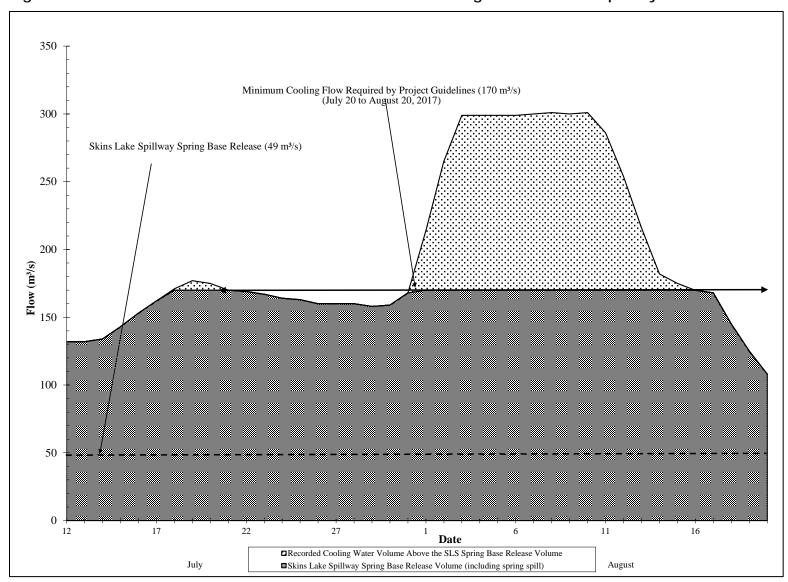

Figure 4. Flows in the Nechako River below Cheslatta Falls resulting from Skins Lake Spillway releases

4.3 Application of the STMP Release Criteria

The Summer Water Temperature and Flow Management Project flow release decisions can be sensitive to the accuracy of meteorological forecasting. If an increase or decrease in temperature occurs over a prolonged period of time (three or four days), inaccurate meteorological forecasts may prematurely predict water temperature fluctuations.

In these instances, it may be required to exercise judgment when applying the Summer Water Temperature and Flow Management Project release criteria using the three water temperature trends. This judgment is based on experience gained in the operation of the Summer Water Temperature and Flow Management Project since 1984 and may result in exceptions to the decision based on strict adherence to the release criteria. One exception was made to the application of the release criteria in 2017.

On August 9, 2017, two of three water temperature trends indicated the water temperature would not exceed 19.4°C in the Nechako River above Stuart River within the forecast period (5 days). The remaining trend, however, showed that the water temperature could be more than 19.4°C within the forecast period. Following these release criteria under these conditions, the release from Skins Lake Spillway could have been decreased from the current release of 283 m³/s to 14.2 m³/s. However, as there was no strong cooling trend indicated, rather than decrease the discharge, it was conservatively decided to maintain the spillway release at 283 m³/s. A cooling trend was established on August 10 and releases were then decreased in accordance with the Protocol.

4.4 Project Summary

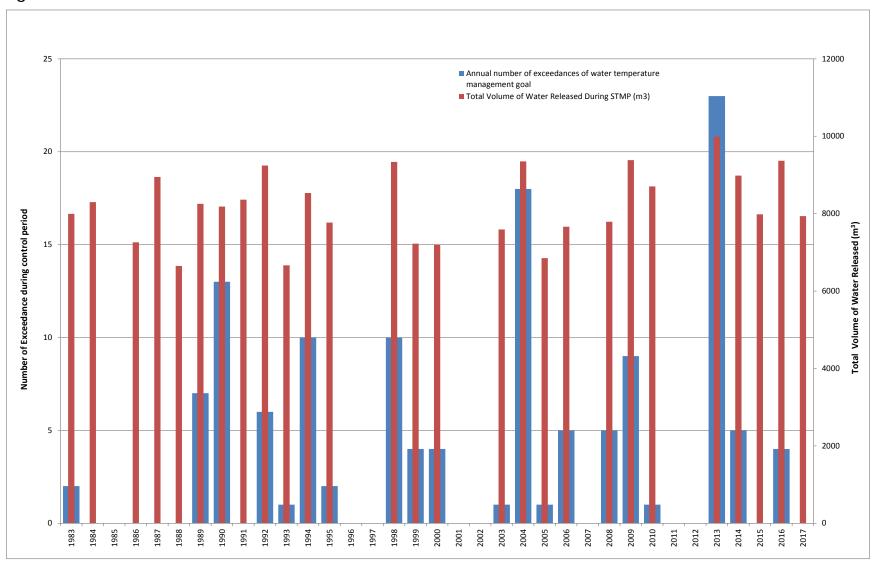

In 2017, mean daily water temperatures in the Nechako River above the Stuart River confluence did not exceed 20.0°C. Oer the duration of the 2017 STMP operational period, the total volume of water released was 7,937.9 m³/s-d, and the average release during the Project was 189 m³/s. The total volume of water released in 2017 was below the calculated average between 1983 and 2017 (8210.9 m³/s-d).

Figure 5 Illustrates the total volume of water used each year the STMP has been implemented and the number of exceedances at the Nechako River above Stuart River during the operational period since the project was initiated in 1983. As shown in Figure 5, the minimum amount of water released during the STMP was in 1988 at 6649.6 m³/s-d and no exceedances were recorded that year. The maximum amount of water released during the STMP since 1983 was in 2013 which had the highest number of exceedances recorded during the control period (23 occurrences). It should be noted that in a number of years (1985, 1991, 1996, 1997, 2001, 2002, 2007 2011 and 2012), because of the need to release excess water from the reservoir that equaled or exceeded the STMP maximum flow criteria in the NRBCF, no annual water release was attributed to the STMP.

It was first assumed that there would be a correlation between the number of exceedances of the water temperature management goal (20°C) and the total volume of water released during the control period; however, as shown in Figure 5 that assumption does not hold true. For example, in 1990 there were a total of 13 exceedances during the control period with 8184.9 m³/s-d total volume.

Typically, weather conditions that increase Nechako River water temperatures cycle over relatively short periods (periods of warming over 4-5 days followed by a cooling trend). Water temperature increases are anticipated by the model predictions and increased releases from the reservoir are initiated followed by decreases as the weather cools. However, in some summers, even though the model predicts the possibility of warmer weather and increased water temperatures and reservoir releases are increased to maximum values, if the duration of the warm (hot) weather continues past about one week, water temperatures will exceed the temperature management goal. Thus, the number of exceedances of the temperature management goal is more closely correlated with the duration of the warm weather periods (high pressure systems) occurring over the Nechako watershed during the control period.

Figure 5. Historical Total Volume Released and Number of Exceedances in the Nechako River above Stuart River

ENVIRONMENT CANADA FORECAST ISSUED AUG 20/17								

APPENDIX 5

SUMMER WATER TEMPERATURE AND FLOW MANAGEMENT PROJECT RESERVOIR RELEASE VOLUME CALCULATIONS FOR JULY 10 TO AUGUST 20, 2017

2017 STMP Report Appendix 5

Skins Lake Spillway base release for the period July 10 (191) to August 20 (232) = $49.0 \text{ m}^3/\text{s}$ STMP Base Release Volume = (JD 228 - JD 191) * $49.0 + (JD 232 - JD 228) * 14.16 = 1,869.6 \text{ m}^3/\text{s}^*\text{days}$

Time period (Julian Day)	Time (hrs)	Flow Rate (m³/s)	Volume (m³/s*hrs)	
July 10 (191) @ 2400 hrs to July 13 (194) @ 1600 hrs		88.0	144.0	12,672
July 13 (194) @ 1600 hrs to July 18 (199) @ 1600 hrs		120.0	226.5	27,180
July 18 (199) @ 1600 hrs to July 30 (211) @ 1600 hrs		288.0	170.0	48,960
July 30 (211) @ 1600 hrs to Aug 2 (214) @ 1600 hrs		72.0	453.1	32,623
Aug 2 (214) @ 1600 hrs to Aug 10 (222) @ 1600 hrs		192.0	283.0	54,336
Aug 10 (222) @ 1600 hrs to Aug 13 (225) @ 1600 hrs		72.0	14.2	1,022
Aug 13 (225) @ 1600 hrs to Aug 16 (228) @ 1600 hrs		72.0	170.0	12,240
Aug 16 (228) @ 1600 hrs to Aug 20 (232) @ 2400 hrs		104.0	14.2	1,477
	Total	1,008 (42.0 days	s)	190,510
Total Release Volume	= 190,510 m ³ /s*hrs = 7,937.9 m ³ /s*days = 280,328 cfs*days			
Volume Released for Cooling Purposes	= Total Volume - Base Volume = 7,937.9 - 1,869.6 = 6,068.3 m ³ /s*days = 214,302 cfs*days			
Average Release over Summer Management Period (July 10 to August 20)	:	= 7,937.9 m = 189.0 m ³ / = 6,674.5 cf		days
